# Causal Inference Fundamentals

Renyu (Philip) Zhang

1

## From Philosophy to Science

- Causality has been an important philosophical question throughout human civilization ([https://grok.com/share/bGVnyWN5\\_fabab87f-004e-4711-83bf-47e9cb4ba195](https://grok.com/share/bGVnyWN5_fabab87f-004e-4711-83bf-47e9cb4ba195)).
- Neyman (1923) and Rubin (1974) make causality a scientific field of study.
- Causal inference** is the process of determining the **independent, actual effect** of a particular phenomenon that is **part of a larger system**.

## Potential Outcomes Model

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- In total  $n$  subjects, each subject is assigned a binary treatment  $W_i = 0, 1$  and an outcome  $Y_i(W_i)$ .

The individual causal effect of the treatment on the  $i$ -th unit is then<sup>[2]</sup>

$$\Delta_i = Y_i(1) - Y_i(0). \quad (1.1)$$

- Fundamental challenge of causal inference: Only one of  $Y_i(1)$  and  $Y_i(0)$  is observable, so we take average:

$$\bar{\Delta} = \frac{1}{n} \sum_{i=1}^n (Y_i(1) - Y_i(0)) \qquad \qquad \tau = \mathbb{E}_P [Y_i(1) - Y_i(0)]$$

Sample Average Treatment Effect

Average Treatment Effect

$$\hat{\tau}_{DM} := \frac{1}{n_1} \sum_{W_i=1} Y_i - \frac{1}{n_0} \sum_{W_i=0} Y_i, \quad n_w = |\{i : W_i = w\}|$$

Difference-in-Mean (DM) Estimator

## RCT & SUTVA

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Under randomized controlled trials, we impose two additional assumptions:

$$\begin{aligned} Y_i &= Y_i(W_i) & (1.5) \\ W_i &\perp\!\!\!\perp \{Y_i(0), Y_i(1)\} & (\text{random treatment assignment}) \end{aligned}$$

- Stable Unit Treatment Value Assumption (SUTVA) = Consistency + No Interference.
- Usually, we need unbiasedness and statistical consistency first.

Suppose furthermore that the treatment is in fact randomized, i.e., that conditionally all the potential outcomes  $\{Y_i(0), Y_i(1)\}_{i=1}^n$  and the number of treated units  $n_1$ , all units are treated with the same probability:<sup>[3]</sup>

$$\mathbb{P}[W_i = 1 \mid \{Y_i(0), Y_i(1)\}_{i=1}^n, n_1] = \frac{n_1}{n}, \quad i = 1, \dots, n. \quad (1.6)$$

Then  $\hat{\tau}_{DM}$  is finite-sample unbiased for the SATE as defined in (1.2).

**Theorem 1.1.** Under assumptions (1.5) and (1.6),

$$\mathbb{E}[\hat{\tau}_{DM} \mid \{Y_i(0), Y_i(1)\}_{i=1}^n, n_0 > 0, n_1 > 0] = \bar{\Delta}. \quad (1.7)$$

5

5

## Statistical Inference with RCT

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- If the treatment assignment is randomized as a Bernoulli trial,

$$W_i \mid \{Y_i(0), Y_i(1)\} \stackrel{\text{iid}}{\sim} \text{Bernoulli}(\pi), \quad 0 < \pi < 1. \quad (1.8)$$

- Then we have a central limit theorem (CLT), or root-n consistency:

**Theorem 1.2.** Under the assumptions of Theorem 1.2, suppose furthermore that the potential outcomes are drawn as  $\{Y_i(0), Y_i(1)\} \stackrel{\text{iid}}{\sim} P$  from a distribution  $P$  with bounded second moments and that we run a Bernoulli trial as in (1.8). Then,

$$\sqrt{n}(\hat{\tau}_{DM} - \tau) \Rightarrow \mathcal{N}(0, V_{DM}), \quad V_{DM} = \frac{\text{Var}[Y_i(0)]}{1-\pi} + \frac{\text{Var}[Y_i(1)]}{\pi}. \quad (1.9)$$

Furthermore, the plug-in variance estimate

$$\hat{V}_{DM} := \frac{n}{n_0^2} \sum_{W_i=0} \left( Y_i - \frac{1}{n_0} \sum_{W_i=0} Y_i \right)^2 + \frac{n}{n_1^2} \sum_{W_i=1} \left( Y_i - \frac{1}{n_1} \sum_{W_i=1} Y_i \right)^2 \quad (1.10)$$

is consistent,  $\hat{V}_{DM} \rightarrow_p V_{DM}$ .

$$\lim_{n \rightarrow \infty} \mathbb{P}\left[\tau \in \left(\hat{\tau}_{DM} \pm \Phi^{-1}(1-\alpha/2)\sqrt{\hat{V}_{DM}/n}\right)\right] = 1 - \alpha$$

6

## RCT as the Gold Standard for Causal Inference

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- We usually say that RCTs are the **gold standard for causal inference**. Why?
- The estimator (DM) is very **simple**.
- It achieves root-n consistency, so we can have valid inference.
- It is unbiased for finite samples (Theorem 1.1 above).

7

## Back to Our Original Causal Inference Problem

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- We have made **three essential assumptions** that make our problem of inferring **ATE** super easy.
  1. Identical and independently distributed (**IID**) samples
  2. Random treatment assignment (**RCT**)
  3. **SUTVA**
- Next, we try to **relax them** one by one.

8

8

## Agenda

- Potential Outcomes Model, RCT and Difference-in-Mean Estimator
- Linear Regression
- Unconfoundedness and Inverse Propensity Weighting
- Augmented Inverse Propensity Weighting and Double Robustness

9

9

## Power of Covariates

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- We now assume that there are some control variables  $X$  in the (linear) data generating process (DGP).

### Linear DGP

$$\begin{aligned}
 Y_i(w) &= \alpha_{(w)} + X_i \cdot \beta_{(w)} + \varepsilon_i(w), \\
 \mathbb{E} [\varepsilon_i(w) | X_i] &= 0, \quad \text{Var} [\varepsilon_i(w) | X_i] = \sigma^2 \\
 \mathbb{P} [W_i = 0] &= \mathbb{P} [W_i = 1] = \frac{1}{2} \quad \mathbb{E} [X] = 0, \quad \text{and define} \quad A = \text{Var} [X]
 \end{aligned}$$

### Linear Regressions under Different Treatment Assignments

Estimator  
for ATE

$$Y_i \sim \alpha_{(0)} + X_i \cdot \beta_{(0)} \text{ for all } i \text{ with } W_i = 0,$$

$$Y_i \sim \alpha_{(1)} + X_i \cdot \beta_{(1)} \text{ for all } i \text{ with } W_i = 1,$$

$$\hat{\tau}_{IREG} = \hat{\alpha}_{(1)} - \hat{\alpha}_{(0)} + \bar{X} (\hat{\beta}_{(1)} - \hat{\beta}_{(0)}).$$

10

10

## Power of Covariates

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- We now assume that the DGP is linear in some control variables  $X$ .

CLT for OLS

$$\sqrt{n_w} \left( \begin{pmatrix} \hat{\alpha}_{(w)} \\ \hat{\beta}_{(w)} \end{pmatrix} - \begin{pmatrix} \alpha_{(w)} \\ \beta_{(w)} \end{pmatrix} \right) \Rightarrow \mathcal{N} \left( 0, \sigma^2 \begin{pmatrix} 1 & 0 \\ 0 & A^{-1} \end{pmatrix} \right)$$

CLT for IREG

$$\hat{\tau}_{IREG} - \tau = \underbrace{\hat{\alpha}_{(1)} - \alpha_{(1)}}_{\approx \mathcal{N}(0, \sigma^2/n_1)} - \underbrace{\hat{\alpha}_{(0)} - \alpha_{(0)}}_{\approx \mathcal{N}(0, \sigma^2/n_0)} + \underbrace{\bar{X} (\beta_{(1)} - \beta_{(0)})}_{\approx \mathcal{N}(0, \|\beta_{(1)} - \beta_{(0)}\|_A^2/n)}$$

$$+ \underbrace{\bar{X} (\hat{\beta}_{(1)} - \hat{\beta}_{(0)} - \beta_{(1)} + \beta_{(0)})}_{\mathcal{O}_P(1/n)},$$

$$\sqrt{n} (\hat{\tau}_{IREG} - \tau) \Rightarrow \mathcal{N} (0, V_{IREG}), \quad V_{IREG} = 4\sigma^2 + \|\beta_{(0)} - \beta_{(1)}\|_A^2$$

11

11

## Power of Covariates

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- We now assume that the DGP is linear in some control variables  $X$ .

Variance for DM

$$\begin{aligned} V_{DM} &= \frac{\text{Var}[Y_i(0)]}{0.5} + \frac{\text{Var}[Y_i(1)]}{0.5} \\ &= 2(\text{Var}[X_i \beta_{(0)}] + \sigma^2) + 2(\text{Var}[X_i \beta_{(1)}] + \sigma^2) \\ &= 4\sigma^2 + 2\|\beta_{(0)}\|_A^2 + 2\|\beta_{(1)}\|_A^2 \\ &= 4\sigma^2 + \|\beta_{(0)} + \beta_{(1)}\|_A^2 + \|\beta_{(0)} - \beta_{(1)}\|_A^2, \end{aligned}$$

IREG More Efficient Than DM

$$V_{IREG} = V_{DM} - \|\beta_{(0)} + \beta_{(1)}\|_A^2 \leq V_{DM}$$

12

12

## Non-linear DGPs

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Consider a model where the DGP is non-linear (still random treatment assignment).

### Non-linear DGP

$$\mu_{(w)}(x) = \mathbb{E} [Y_i(w) | X_i = x], \quad \sigma_{(w)}^2(x) = \text{Var} [Y_i(w) | X_i = x]$$

$$\mathbb{P}[W_i = 1] = \pi \quad \mathbb{E}[X] = 0, \quad \text{and define } A = \text{Var}[X]$$

### Variance of DM

$$\sqrt{n}(\hat{\tau}_{DM} - \tau) \Rightarrow \mathcal{N}(0, V_{DM}) = 4\sigma^2 + 2\text{Var}[\mu_{(0)}(X_i)] + 2\text{Var}[\mu_{(1)}(X_i)]$$

### Same Estimator for ATE

$$Y_i \sim \alpha_{(0)} + X_i \cdot \beta_{(0)} \text{ for all } i \text{ with } W_i = 0,$$

$$Y_i \sim \alpha_{(1)} + X_i \cdot \beta_{(1)} \text{ for all } i \text{ with } W_i = 1,$$

$$\hat{\tau}_{IREG} = \hat{\alpha}_{(1)} - \hat{\alpha}_{(0)} + \bar{X} (\hat{\beta}_{(1)} - \hat{\beta}_{(0)}).$$

13

13

## Non-linear DGPs

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Consider a model where the DGP is non-linear (still random treatment assignment).

### Best Linear Projection Coefficients

$$(\alpha_{(w)}^*, \beta_{(w)}^*) = \underset{\alpha, \beta}{\operatorname{argmin}} \left\{ \mathbb{E} [(Y_i(w) - \alpha - X_i \cdot \beta)^2] \right\}$$

### CLT for IREG

**Theorem 1.3.** Under the conditions of Theorem 1.2, assume furthermore that  $\mathbb{E}[X'X]$  is invertible. Then,

$$\begin{aligned} \sqrt{n}(\hat{\tau}_{IREG} - \tau) &\Rightarrow \mathcal{N}(0, V_{IREG}), \\ V_{IREG} &= \text{Var}[X_i \cdot (\beta_{(1)}^* - \beta_{(0)}^*)] + \frac{1}{\pi} \mathbb{E} [(Y_i(1) - \alpha_{(1)}^* - X_i \cdot \beta_{(1)}^*)^2] \\ &\quad + \frac{1}{1-\pi} \mathbb{E} [(Y_i(0) - \alpha_{(0)}^* - X_i \cdot \beta_{(0)}^*)^2]. \end{aligned} \quad (1.23)$$

14

14

## Where Amazing Happens

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Consider a model where the DGP is **non-linear** (still random treatment assignment).

$$\begin{aligned}
 V_{IREG} &= 2MSE_{(0)}^* + 2MSE_{(1)}^* + \|\beta_{(1)}^* - \beta_{(0)}^*\|_A^2 & \hat{\tau}_{IREG} &= \frac{1}{n} \sum_{i=1}^n \left( \underbrace{(\hat{\alpha}_{(1)} + X_i \hat{\beta}_{(1)})}_{\hat{\mu}_{(1)}(X_i)} - \underbrace{(\hat{\alpha}_{(0)} + X_i \hat{\beta}_{(0)})}_{\hat{\mu}_{(0)}(X_i)} \right) \\
 &= 4\sigma^2 + 2 \text{Var} [\mu_{(0)}(X) - X\beta_{(0)}^*] & & \text{Another Perspective:} \\
 &\quad + 2 \text{Var} [\mu_{(1)}(X) - X\beta_{(1)}^*] + \|\beta_{(1)}^* - \beta_{(0)}^*\|_A^2 & & \text{Difference in Predictions} \\
 &= 4\sigma^2 + 2 (\text{Var} [\mu_{(0)}(X)] - \text{Var} [X\beta_{(0)}^*]) \\
 &\quad + 2 (\text{Var} [\mu_{(1)}(X)] - \text{Var} [X\beta_{(1)}^*]) + \|\beta_{(1)}^* - \beta_{(0)}^*\|_A^2 \\
 &= 4\sigma^2 + 2 (\text{Var} [\mu_{(0)}(X)] + \text{Var} [\mu_{(1)}(X)]) \\
 &\quad + \|\beta_{(1)}^* - \beta_{(0)}^*\|_A^2 - 2 \|\beta_{(0)}^*\|_A^2 - 2 \|\beta_{(1)}^*\|_A^2 \\
 &= 4\sigma^2 + 2 (\text{Var} [\mu_{(0)}(X)] + \text{Var} [\mu_{(1)}(X)]) - \|\beta_{(0)}^* + \beta_{(1)}^*\|_A^2 \\
 &= V_{DM} - \|\beta_{(0)}^* + \beta_{(1)}^*\|_A^2.
 \end{aligned}$$

$\pi = 0.5$   
 $\sigma_{(1)}^2(x) = \sigma_{(0)}^2(x) = \sigma^2$  for all  $x$

15

## RCT Recap

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Causal inference is to infer about a parallel world, so it must rely on taking averages.
- RCT is the gold standard for causal inference, thanks to 3 important assumptions.
  - IID
  - RCT
  - SUTVA
- DM estimator in RCT is root-n consistent and unbiased.
- With informative covariates, IREG estimator based on OLS is more efficient than DM estimator, even when the model is mis-specified.

**Abstract.** Measuring the causal effects of digital advertising remains challenging despite the availability of granular data. Unobservable factors make exposure endogenous, and advertising's effect on outcomes tends to be small. In principle, these concerns could be addressed using randomized controlled trials (RCTs). In practice, few online ad campaigns rely on RCTs and instead use observational methods to estimate ad effects. We assess empirically whether the variation in data typically available in the advertising industry enables observational methods to recover the causal effects of online advertising. Using data from 15 U.S. advertising experiments at Facebook comprising 500 million user-experiment observations and 1.6 billion ad impressions, we contrast the experimental results to those obtained from multiple observational models. The observational methods often fail to produce the same effects as the randomized experiments, even after conditioning on extensive demographic and behavioral variables. In our setting, advances in causal inference methods do not allow us to isolate the exogenous variation needed to estimate the treatment effects. We also characterize the incremental explanatory power our data would require to enable observational methods to successfully measure advertising effects. Our findings suggest that commonly used observational approaches based on the data usually available in the industry often fail to accurately measure the true effect of advertising.

# What If RCT is Missing?

## LaLonde (1986) after Nearly Four Decades:

### Lessons Learned

Guido Imbens Yiqing Xu

June 4, 2024

#### Abstract

In 1986, Robert LaLonde published an article that compared nonexperimental estimates to experimental benchmarks (LaLonde 1986). He concluded that the non-experimental methods at the time could not systematically replicate experimental benchmarks, casting doubt on the credibility of these methods. Following LaLonde's critical assessment, there have been significant methodological advances and practical changes, including (i) an emphasis on estimators based on unconfoundedness, (ii) a focus on the importance of overlap in covariate distributions, (iii) the introduction of propensity score-based methods leading to doubly robust estimators, (iv) a greater emphasis on validation exercises to bolster research credibility, and (v) methods for estimating and exploiting treatment effect heterogeneity. To demonstrate the practical lessons from these advances, we reexamine the LaLonde data and the Imbens-Rubin-Sacerdote lottery data. We show that modern methods, when applied in contexts with significant covariate overlap, yield robust estimates for the adjusted differences between the treatment and control groups. However, this does not mean that these estimates are valid. To assess their credibility, validation exercises (such as placebo tests) are essential, whereas goodness of fit tests alone are inadequate. Our findings highlight the importance of closely examining the assignment process, carefully inspecting overlap, and conducting validation exercises when analyzing causal effects with nonexperimental data.

LaLonde (1986) after Nearly Four Decades: <https://arxiv.org/abs/2406.00827>

- Understanding the treatment assignment mechanism is critical.
- Unconfounded data + overlapping + modern methods yield robust, not necessarily valid, estimates.
- Validation exercises, such as placebo tests before treatment, are essential.
- Begin analyses of causal effects with an effort to understand the assignment mechanism. A clear grasp of the “design” is crucial for the credibility of the unconfoundedness assumption.
- Estimate the propensity score using a flexible method. Assess overlap by plotting the distributions of propensity scores for treated and control units. Trim the data based on the propensity score to make the groups more comparable.
- Apply modern methods, such as doubly-robust estimators, to estimate the average causal effects. Explore alternative estimands, such as the conditional average treatment effects and quantile treatment effects.
- Perform placebo tests, such as those using pretreatment outcomes, to validate unconfoundedness. Conduct sensitivity analyses to gauge the robustness of the findings.

## What if We Have No Randomized Assignment

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Simpson's Paradox: [https://en.wikipedia.org/wiki/Simpson%27s\\_paradox](https://en.wikipedia.org/wiki/Simpson%27s_paradox)

- **Simpson's Paradox** is a notorious example where RCT is violated.
- Solution: Aggregate DM estimates from different groups by sample size weights.
- **Unconfoundedness:** Conditional independence assumption (**CIA**, the most common, but also very strong, assumption in observational studies):

Treatment Stone size	Treatment A	Treatment B
Small stones	Group 1 93% (81/87)	Group 2 87% (234/270)
Large stones	Group 3 73% (192/263)	Group 4 69% (55/80)
Both	78% (273/350)	83% (289/350)

$\{Y_i(0), Y_i(1)\} \perp\!\!\!\perp W_i \mid X_i = x$ , for all  $x \in \mathcal{X}$   You observe all potential confounders.

- Conditional Average Treatment Effect (CATE):  $\tau(x) = \mathbb{E}[Y_i(1) - Y_i(0) \mid X_i = x]$
- Stratified estimator:  $\hat{\tau}_{STRAT} = \sum_{x \in \mathcal{X}} \frac{n_x}{n} \hat{\tau}(x)$ ,  $\hat{\tau}(x) = \frac{1}{n_{x1}} \sum_{\{X_i=x, W_i=1\}} Y_i - \frac{1}{n_{x0}} \sum_{\{X_i=x, W_i=0\}} Y_i$   
 where  $n_x = |\{i : X_i = x\}|$  and  $n_{xw} = |\{i : X_i = x, W_i = w\}|$

## Stratified Estimator

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Is the **Stratified Estimator** convergent?
  - CLT for each stratum:

$$\sqrt{n_x} (\hat{\tau}(x) - \tau(x)) \Rightarrow \mathcal{N} \left( 0, \frac{\sigma_{(1)}^2}{e(x)} + \frac{\sigma_{(0)}^2(x)}{1 - e(x)} \right)$$

$\sigma_{(w)}^2(x) = \text{Var}[Y_i(w) | X_i = x]$   
 $e(x) = \mathbb{P}[W_i = 1 | X_i = x]$   
 $\tau(x) = \mathbb{E}[Y_i(1) - Y_i(0) | X_i = x]$

Propensity Score (PS) ←

Stratified Estimator is **root-n consistent**:

**Theorem 2.1.** Suppose that  $\{X_i, Y_i(0), Y_i(1), W_i\} \stackrel{\text{na}}{\sim} P$  for some distribution  $P$  where  $X_i$  takes values in a finite cardinality set  $\mathcal{X}$  and potential outcomes have bounded second moments conditionally on  $X_i$ . Suppose furthermore that both (2.1) and SUTVA hold, and that there is non-trivial treatment variation for each  $x \in \mathcal{X}$ , i.e., writing  $e(x) = \mathbb{P}[W_i = 1 | X_i = x]$ , we have  $0 < e(x) < 1$  for all  $x$ . Then, using notation as in (1.21),

(2.1): Unconfoundedness

$$\{Y_i(0), Y_i(1)\} \perp\!\!\!\perp W_i | X_i = x, \quad \text{for all } x \in \mathcal{X} \quad \sqrt{n}(\hat{\tau}_{\text{STRAT}} - \tau) \Rightarrow \mathcal{N}(0, V_{\text{STRAT}})$$

$$V_{\text{STRAT}} = \text{Var}[\tau(X_i)] + \mathbb{E} \left[ \frac{\sigma_{(1)}^2(X_i)}{e(X_i)} + \frac{\sigma_{(0)}^2(X_i)}{1 - e(X_i)} \right]. \quad (2.4)$$

21

21

## Stratified Estimator & Propensity Score

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Stratified estimator is just **propensity score estimation on a discrete set**.
  - What if the covariates are **continuous**?
- Unconfoundedness:**  $\{Y_i(0), Y_i(1)\} \perp\!\!\!\perp W_i | X_i,$  (2.5)

Statistically, a key property of the propensity score is that it is a balancing score: If (2.5) holds, then in fact

$$\{Y_i(0), Y_i(1)\} \perp\!\!\!\perp W_i | e(X_i), \quad (2.7)$$

i.e., it actually suffices to control for  $e(X)$  rather than  $X$  to remove biases associated with a non-random treatment assignment. We can verify this claim as follows:

$$\begin{aligned} & \mathbb{P}[W_i = w | \{Y_i(0), Y_i(1)\}, e(X_i)] \\ &= \int_{\mathcal{X}} \mathbb{P}[W_i = w | \{Y_i(w)\}, X_i = x] \mathbb{P}[X_i = x | \{Y_i(w)\}, e(X_i)] dx \\ &= \int_{\mathcal{X}} \mathbb{P}[W_i = w | X_i = x] \mathbb{P}[X_i = x | \{Y_i(w)\}, e(X_i)] dx \quad (\text{unconf.}) \\ &= \begin{cases} e(X_i) & \text{if } w = 1, \\ 1 - e(X_i) & \text{else.} \end{cases} \end{aligned}$$

- Overlapping assumption:**  $\eta \leq e(x) \leq 1 - \eta$  for all  $x \in \mathcal{X}$

22

22

## Propensity Stratification

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

Imbens, G.W. and Rubin, D.B., 2015. *Causal inference in statistics, social, and biomedical sciences*.

Rosenbaum, P.R. and Rubin, D.B., 1983. The central role of the propensity score in observational studies for causal effects. *Biometrika*, 70(1), pp.41-55.

**Propensity stratification** One instantiation of this idea is propensity stratification, which proceeds as follows. First obtain an estimate  $\hat{e}(x)$  of the propensity score via non-parametric regression, and choose a number of strata  $J$ . Then:

- Sort the observations according to their propensity scores, such that

$$\hat{e}(X_{i_1}) \leq \hat{e}(X_{i_2}) \leq \dots \leq \hat{e}(X_{i_n}). \quad (2.8)$$

- Split the sample into  $J$  evenly size strata using the sorted propensity score and, in each stratum  $j = 1, \dots, J$ , compute the simple difference-in-means treatment effect estimator for the stratum:

$$\hat{\tau}_j = \frac{\sum_{j=\lfloor(j-1)n/J\rfloor+1}^{\lfloor jn/J\rfloor} W_i Y_i}{\sum_{j=\lfloor(j-1)n/J\rfloor+1}^{\lfloor jn/J\rfloor} W_i} - \frac{\sum_{j=\lfloor(j-1)n/J\rfloor+1}^{\lfloor jn/J\rfloor} (1 - W_i) Y_i}{\sum_{j=\lfloor(j-1)n/J\rfloor+1}^{\lfloor jn/J\rfloor} (1 - W_i)}. \quad (2.9)$$

- Estimate the average treatment by applying the idea of (2.3) across strata:

$$\hat{\tau}_{PSTRAT} = \frac{1}{J} \sum_{j=1}^J \hat{\tau}_j. \quad (2.10)$$

Propensity Stratification is consistent when the propensity score estimator is uniformly consistent and the number of strata  $J$  grows appropriately with  $n$ .

Another more popular approach:  
**Propensity Score Matching (PSM)**

- Chapter 15 of Imbens and Rubin (2015)

See Rosenbaum and Rubin (1983) for comprehensive discussions on these two methods which rely on similar assumptions.

23

23

## Inverse Propensity Weighting (IPW)

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Another common way of using propensity score is the IPW estimator:

$$\hat{\tau}_{IPW} = \frac{1}{n} \sum_{i=1}^n \left( \frac{W_i Y_i}{\hat{e}(X_i)} - \frac{(1 - W_i) Y_i}{1 - \hat{e}(X_i)} \right)$$

- To analyze this estimator, it is convenient to compare it to an oracle where the actual propensity score is known, because these two estimators' difference can be bounded by the performance of PS estimator:

$$\hat{\tau}_{IPW}^* = \frac{1}{n} \sum_{i=1}^n \left( \frac{W_i Y_i}{e(X_i)} - \frac{(1 - W_i) Y_i}{1 - e(X_i)} \right)$$

- A related concept, Horvitz-Thompson estimator: [https://grok.com/share/bGVnYWN5\\_2e4d6004-5e65-4cb4-82d8-8c5aa6bc3218](https://grok.com/share/bGVnYWN5_2e4d6004-5e65-4cb4-82d8-8c5aa6bc3218)

24

24

## Performance of IPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

**Theorem 2.2.** Suppose that  $\{X_i, Y_i(0), Y_i(1), W_i\} \stackrel{iid}{\sim} P$ , that both (2.5) and SUTVA hold, and that all moments used in the expression for  $V_{IPW^*}$  below are finite. Then, the oracle IPW estimator is unbiased,  $\mathbb{E}[\hat{\tau}_{IPW}^*] = \tau$ , and

$$\begin{aligned} \sqrt{n}(\hat{\tau}_{IPW}^* - \tau) &\Rightarrow \mathcal{N}(0, V_{IPW^*}) \\ V_{IPW^*} &= \text{Var}[\tau(X_i)] + \mathbb{E}\left[\frac{(\mu_{(0)}(X_i) + (1 - e(X_i))\tau(X_i))^2}{e(X_i)(1 - e(X_i))}\right] \\ &\quad + \mathbb{E}\left[\frac{\sigma_{(1)}^2(X_i)}{e(X_i)} + \frac{\sigma_{(0)}^2(X_i)}{1 - e(X_i)}\right]. \end{aligned} \quad (2.13)$$

Unconfoundedness:

$$\{Y_i(0), Y_i(1)\} \perp\!\!\!\perp W_i \mid X_i, \quad (2.5)$$

Overlapping:

$$\eta \leq e(x) \leq 1 - \eta \text{ for all } x \in \mathcal{X}$$

25

25

## IPW vs. STRAT

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)

- Stratified estimator is a special case of IPW:

$$\hat{\tau}_{STRAT} = \frac{1}{n} \sum_{i=1}^n \left( \frac{W_i Y_i}{\hat{e}(X_i)} - \frac{(1 - W_i) Y_i}{1 - \hat{e}(X_i)} \right), \quad \hat{e}(x) = \frac{n_{x1}}{n_x}$$

- What is interesting is that STRAT is more efficient than IPW:

$$V_{IPW^*} = V_{STRAT} + \mathbb{E}\left[\frac{(\mu_{(0)}(X_i) + (1 - e(X_i))\tau(X_i))^2}{e(X_i)(1 - e(X_i))}\right]$$

- When  $X$  is discrete with a natural but specific propensity model, one feasible IPW can outperform the oracle IPW.
  - This result should not be over-generalized.

26

26

## What's Wrong with IPW?

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fl35/CausalInferenceClass.html>

- If the propensity score  $e(\cdot)$  is unknown, does IPW converge sufficiently fast to ensure semi-parametric efficiency, i.e., root-n consistency or the gap between oracle IPW and general IPW is of order  $o(\sqrt{n})$ ?

Let's try to bound the error using Cauchy-Schwarz:

$$\hat{\tau}_{IPW} = \underbrace{\hat{\tau}_{IPW}^*}_{\text{a good estimator}} + \underbrace{\hat{\tau}_{IPW} - \hat{\tau}_{IPW}^*}_{\text{due to errors in } \hat{e}(\cdot)}.$$

$$\begin{aligned} \hat{\tau}_{IPW} - \hat{\tau}_{IPW}^* &= \frac{1}{n} \sum_{i=1}^n \left( \left( \frac{W_i}{\hat{e}(X_i)} - \frac{(1-W_i)}{1-\hat{e}(X_i)} \right) - \left( \frac{W_i}{e(X_i)} - \frac{(1-W_i)}{1-e(X_i)} \right) \right) Y_i \\ &\leq \sqrt{\frac{1}{n} \sum_{i=1}^n \left( \left( \frac{W_i}{\hat{e}(X_i)} - \frac{(1-W_i)}{1-\hat{e}(X_i)} \right) - \left( \frac{W_i}{e(X_i)} - \frac{(1-W_i)}{1-e(X_i)} \right) \right)^2} \\ &\quad \times \sqrt{\frac{1}{n} \sum_{i=1}^n Y_i^2} \\ &\asymp \sqrt{\frac{1}{n} \sum_{i=1}^n (\hat{e}(X_i) - e(X_i))^2}. \end{aligned}$$

- Not good enough!
- For most ML algorithms, RMSE  $\gg \sqrt{1/n}$ .
- So the second term is non-negligible in finite samples.
- This naïve plug-in IPW will generally produce invalid confidence intervals.

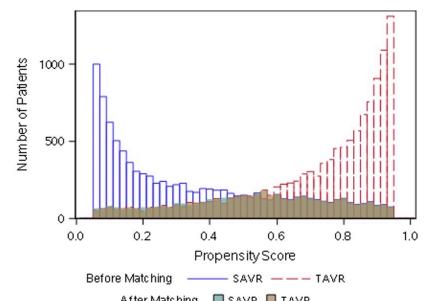

27

27

## Overlapping Assumption $\eta \leq e(x) \leq 1 - \eta$ for all $x \in \mathcal{X}$

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Imbens, G.W. and Rubin, D.B., 2015. *Causal inference in statistics, social, and biomedical sciences*.  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fl35/CausalInferenceClass.html>

- Overlapping assumption is important, both theoretically and practically, but we often do not have overlapping.
  - Severe weights in extreme cases, which lead to biases in estimates.
  - Estimating ATE becomes impossible, but only the ATE on overlapping samples (i.e., conditional ATE).
- Adjustments methods
  - Regression: Model sensitive to extreme data
  - Matching: Many samples are excluded
  - Stratification: Adds bias due to residual imbalance within strata
- Trimming
  - Remove data samples with PS outside  $[a, 1-a]$ ,  $a=0.1$  as a baseline.
  - Further remove data samples whose PS is below  $q$ -quantile of treated units.
  - Further remove data samples whose PS is above  $(1-q)$ -quantile of control units.
  - Winsorize all PS below  $a$  to  $a$  and above  $1-a$  to  $1-a$ .

28

28

## Balancing Weights

Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fl35/CausalInferenceClass.html>  
 Balancing covariates via propensity score weighting: <https://arxiv.org/abs/1404.1785>

- IPW is a special case of balancing weights.
  - Assume density of the observed covariates,  $f(x)$ , exists wrt a measure  $\mu$
  - Consider a target population, denoted by a density  $g(x)$ , possibly different from  $f(x)$
  - The ratio  $h(x) = g(x)/f(x)$  is called a *tilting function*, which re-weights the observed sample to represent the target population
  - A new class of estimands: **the ATE over the target population  $g$**

$$\tau_h \equiv \mathbb{E}_g [Y_i(1) - Y_i(0)] = \frac{\int \tau(x) f(x) h(x) \mu(dx)}{\int f(x) h(x) \mu(dx)} = \frac{\mathbb{E}\{h(x)\tau(x)\}}{\mathbb{E}\{h(x)\}}$$

29

29

## Balancing Weights

Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fl35/CausalInferenceClass.html>  
 Balancing covariates via propensity score weighting: <https://arxiv.org/abs/1404.1785>

- Different weighting schemes:

target population	$h(x)$	estimand	weight ( $w_1, w_0$ )
combined	1	ATE	$\left(\frac{1}{e(x)}, \frac{1}{1-e(x)}\right)$ [HT]
treated	$e(x)$	ATT	$\left(1, \frac{e(x)}{1-e(x)}\right)$
control	$1 - e(x)$	ATC	$\left(\frac{1-e(x)}{e(x)}, 1\right)$
overlap	$e(x)(1 - e(x))$	ATO	$(1 - e(x), e(x))$
truncated combined	$1(\alpha < e(x) < 1 - \alpha)$		$\left(\frac{1(\alpha < e(x) < 1 - \alpha)}{e(x)}, \frac{1(\alpha < e(x) < 1 - \alpha)}{1 - e(x)}\right)$
matching	$\min\{e(x), 1 - e(x)\}$		$\left(\frac{\min\{e(x), 1 - e(x)\}}{e(x)}, \frac{\min\{e(x), 1 - e(x)\}}{1 - e(x)}\right)$

$$\hat{\tau}_h = \frac{\sum_i w_1(x_i) Z_i Y_i}{\sum_i w_1(x_i) Z_i} - \frac{\sum_i w_0(x_i) (1 - Z_i) Y_i}{\sum_i w_0(x_i) (1 - Z_i)}$$

Table 1: Examples of balancing weights and corresponding target population and estimand under different  $h$ .

**Theorem 1.**  $\hat{\tau}_h$  is a consistent estimator of  $\tau_h$ .

## Augmented Inverse Propensity Weighting (AIPW)

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmle-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmle-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fi35/CausalInferenceClass.html>

- The performance of IPW estimators depends on:
  - The performance of PS estimator
  - The weighting mechanisms (regression, matching, stratification, etc.)
- Can we improve IPW with machine learning?
- Yes, with new doubly robust estimators: Augmented Inverse Propensity Weighting.
- Two consistent characterizations of ATE: IPW and nonparametric regression.

### Nonparametric Regression

$$\begin{aligned}\tau(x) &:= \mathbb{E}[Y_i(1) - Y_i(0) \mid X_i = x] \\ &= \mathbb{E}[Y_i(1) \mid X_i = x] - \mathbb{E}[Y_i(0) \mid X_i = x] \\ &= \mathbb{E}[Y_i(1) \mid X_i = x, W_i = 1] - \mathbb{E}[Y_i(0) \mid X_i = x, W_i = 0] \quad (\text{unconf}) \\ &= \mathbb{E}[Y_i \mid X_i = x, W_i = 1] - \mathbb{E}[Y_i \mid X_i = x, W_i = 0] \quad (\text{SUTVA}) \\ &= \mu_{(1)}(x) - \mu_{(0)}(x),\end{aligned}$$

$$\tau = \mathbb{E}[\mu_{(1)}(X_i) - \mu_{(0)}(X_i)]$$

$$\hat{\tau}_{REG} = n^{-1} \sum_{i=1}^n (\hat{\mu}_{(1)}(X_i) - \hat{\mu}_{(0)}(X_i))$$

### IPW

$$\tau = \mathbb{E}[\hat{\tau}_{IPW}^*], \quad \hat{\tau}_{IPW}^* = \frac{1}{n} \sum_{i=1}^n \left( \frac{W_i Y_i}{e(X_i)} - \frac{(1 - W_i) Y_i}{1 - e(X_i)} \right)$$

Estimation of regression coefficients when some regressors are not always observed

## Double Robustness of AIPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fi35/CausalInferenceClass.html>

$$\hat{\tau}_{AIPW} = \frac{1}{n} \sum_{i=1}^n \left( \hat{\mu}_{(1)}(X_i) - \hat{\mu}_{(0)}(X_i) + W_i \frac{Y_i - \hat{\mu}_{(1)}(X_i)}{\hat{e}(X_i)} - (1 - W_i) \frac{Y_i - \hat{\mu}_{(0)}(X_i)}{1 - \hat{e}(X_i)} \right)$$

- Weak double robustness (DR): If either  $\hat{\mu}_{(w)}(x) \approx \mu_{(w)}(x)$  or  $\hat{e}(x) \approx e(x)$ , AIPW is consistent.

$$\begin{aligned} \hat{\tau}_{AIPW} &= \underbrace{\frac{1}{n} \sum_{i=1}^n (\hat{\mu}_{(1)}(X_i) - \hat{\mu}_{(0)}(X_i))}_{\text{the regression estimator}} + \underbrace{\frac{1}{n} \sum_{i=1}^n \left( \frac{W_i}{\hat{e}(X_i)} (Y_i - \hat{\mu}_{(1)}(X_i)) - \frac{1 - W_i}{1 - \hat{e}(X_i)} (Y_i - \hat{\mu}_{(0)}(X_i)) \right)}_{\approx \text{mean-zero noise}} \\ &\quad \hat{\tau}_{AIPW} = \underbrace{\frac{1}{n} \sum_{i=1}^n \left( \frac{W_i Y_i}{\hat{e}(X_i)} - \frac{(1 - W_i) Y_i}{1 - \hat{e}(X_i)} \right)}_{\text{the IPW estimator}} + \underbrace{\frac{1}{n} \sum_{i=1}^n \left( \hat{\mu}_{(1)}(X_i) \left( 1 - \frac{W_i}{\hat{e}(X_i)} \right) - \hat{\mu}_{(0)}(X_i) \left( 1 - \frac{1 - W_i}{1 - \hat{e}(X_i)} \right) \right)}_{\approx \text{mean-zero noise}} \end{aligned}$$

- Strong double robustness: root-n consistency and CLT.

33

33

## Strong Double Robustness of AIPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~fi35/CausalInferenceClass.html>

- More interesting and useful strong double robustness: If the black-box predictors of mean and propensity score are reasonably good (i.e., converge to the ground-truth reasonably fast), AIPW is root-n consistent.

consistency statement given above. At a high level, strong double robustness is a claim that results of the following type exist: If we use estimators  $\hat{\mu}_{(w)}(x)$  and  $\hat{e}(x)$  that are both consistent with root-mean squared error (RMSE) decaying faster than  $n^{-\alpha_\mu}$  and  $n^{-\alpha_e}$  respectively, and if furthermore  $\alpha_\mu + \alpha_e \geq 1/2$ , then

$$\sqrt{n}(\hat{\tau}_{AIPW} - \tau) \Rightarrow \mathcal{N}(0, V_{AIPW}),$$

$$V_{AIPW} = \text{Var}[\tau(X_i)] + \mathbb{E}\left[\frac{\sigma_0^2(X_i)}{1 - e(X_i)}\right] + \mathbb{E}\left[\frac{\sigma_1^2(X_i)}{e(X_i)}\right]. \quad (3.5)$$

The reason this meta-result holds is that, in general, if the RMSE of  $\hat{\mu}_{(w)}(x)$  decays faster than  $n^{-\alpha_\mu}$  and the RMSE of  $\hat{e}(x)$  decays faster than  $n^{-\alpha_e}$ , then the bias of AIPW decays faster than  $n^{-(\alpha_\mu + \alpha_e)}$ ; and, in particular, if  $\alpha_\mu + \alpha_e \geq 1/2$  then the bias is lower-order on the  $1/\sqrt{n}$ -scale. What's remarkable about this result is that, under the same conditions, the bias of the regression estimator would in general only be bounded to order  $n^{-\alpha_\mu}$  and that of IPW to order  $n^{-\alpha_e}$ ; and so the AIPW construction succeeds in making bias substantially smaller than what either the regression or IPW estimators could achieve on their own.<sup>17</sup>

$$\mathbb{E}[(\hat{\mu}_{(w)}(X) - \mu_{(w)}(X))^2]^{\frac{1}{2}}, \mathbb{E}[(\hat{e}(X) - e(X))^2]^{\frac{1}{2}} \ll \frac{1}{\sqrt{n}}$$

Can be generalized to order  $n^{-\alpha_\mu}$  and  $n^{-\alpha_e}$

Then the error of AIPW will be of order  $n^{-(\alpha_\mu + \alpha_e)}$

As long as  $\alpha_\mu + \alpha_e \geq 1/2$ , the error of AIPW is smaller than  $o(n^{-1/2})$ , establishing the desired root-n consistency.

This is the core idea of double machine learning (DML).

34

34

## AIPW vs. IPW

 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- If we need naïve plug-in IPW to be root-n consistent and produce invalid confidence intervals, the underlying ML PS estimates should have  $o(n^{-1/2})$  L2-norm error (sometimes called parametric rate), which is too optimistic in most real-world applications.
- For AIPW, it suffices for conditional mean and PS estimates to achieve  $o(n^{-1/4})$  L2-norm error (sometimes called semiparametric efficient), which is realistic and pretty accurate for complex ML methods.
- AIPW translates natural and realistic assumptions on ML estimates accuracy into valid inference.
- For AIPW, we only need one moment condition to be true, and the convergency speed of the final estimator is the product of convergence speed of both estimators.

## AIPW vs. IPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

$\hat{\theta}(x)$ : estimators for conditional mean and propensity score.

36

36

## AIPW Asymptotic Normality

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- Like IPW, we first establish the root-n consistency of **oracle AIPW**, who has access to the ground-truth conditional mean and propensity score.

$$\hat{\tau}_{AIPW}^* = \frac{1}{n} \sum_{i=1}^n \Gamma_i$$

$$\Gamma_i = \mu_{(1)}(X_i) - \mu_{(0)}(X_i) + W_i \frac{Y_i - \mu_{(1)}(X_i)}{e(X_i)} - (1 - W_i) \frac{Y_i - \mu_{(0)}(X_i)}{1 - e(X_i)}$$

**Proposition 3.1.** Under the basic setting with SUTVA, unconfoundedness and strong overlap given at the beginning of this chapter, the oracle AIPW estimator has the limit distribution given in (3.5), i.e.,

$$\sqrt{n} (\hat{\tau}_{AIPW}^* - \tau) \Rightarrow \mathcal{N}(0, V_{AIPW}). \quad (3.7)$$

$$V_{AIPW} = \text{Var} [\tau(X_i)] + \mathbb{E} \left[ \frac{\sigma_0^2(X_i)}{1 - e(X_i)} \right] + \mathbb{E} \left[ \frac{\sigma_1^2(X_i)}{e(X_i)} \right]. \quad (3.5)$$

- Hence, it suffices to show that if  $\hat{\mu}_{(w)}(\cdot)$  and  $\hat{e}(\cdot)$  converge to the ground-truth fast enough:

$$\sqrt{n} (\hat{\tau}_{AIPW} - \hat{\tau}_{AIPW}^*) \rightarrow_p 0$$

- To obtain this root-n equivalence between AIPW and oracle AIPW, we leverage the idea of **cross-fitting**.

37

37

## Cross Fitting

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- For AIPW, we typically have two steps of estimation:
  - First, we predict the mean responses and propensity scores using ML.
  - Then, we use these predictions to estimate the ATE via AIPW.
- Cross-fitting** is a common strategy for AIPW:
  - Split the data into two samples: One sample for ML prediction and the other sample to use ML predictions and data to construct AIPW estimators.

Train	Infer	
-------	-------	--

$$\hat{\tau}_{AIPW} = \frac{|\mathcal{I}_1|}{n} \hat{\tau}^{\mathcal{I}_1} + \frac{|\mathcal{I}_2|}{n} \hat{\tau}^{\mathcal{I}_2}, \quad \hat{\tau}^{\mathcal{I}_1} = \frac{1}{|\mathcal{I}_1|} \sum_{i \in \mathcal{I}_1} \left( \hat{\mu}_{(1)}^{\mathcal{I}_2}(X_i) - \hat{\mu}_{(0)}^{\mathcal{I}_2}(X_i) \right. \\ \left. + W_i \frac{Y_i - \hat{\mu}_{(1)}^{\mathcal{I}_2}(X_i)}{\hat{e}^{\mathcal{I}_2}(X_i)} - (1 - W_i) \frac{Y_i - \hat{\mu}_{(0)}^{\mathcal{I}_2}(X_i)}{1 - \hat{e}^{\mathcal{I}_2}(X_i)} \right), \quad (3.9)$$

Infer	Train	
-------	-------	--

where the  $\hat{\mu}_{(w)}^{\mathcal{I}_2}(\cdot)$  and  $\hat{e}^{\mathcal{I}_2}(\cdot)$  are estimates of  $\mu_{(w)}(\cdot)$  and  $e(\cdot)$  obtained using only the half-sample  $\mathcal{I}_2$ , and  $\hat{\tau}^{\mathcal{I}_2}$  is defined analogously (with the roles of  $\mathcal{I}_1$  and  $\mathcal{I}_2$  swapped). In other words,  $\hat{\tau}^{\mathcal{I}_1}$  is a treatment effect estimator on  $\mathcal{I}_1$  that uses  $\mathcal{I}_2$  to estimate its nuisance components, and vice-versa.

- The "honest" regression residual (different training and inference data) cannot be artificially shrunk by overfitting.

38

38

## Back to AIPW Asymptotic Normality

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- Under cross-fitting and  $\hat{\mu}_{(w)}(\cdot)$  and  $\hat{e}(\cdot)$  converging to ground-truth sufficiently fast, we have the root-n equivalence between AIPW and oracle AIPW.

**Theorem 3.2.** Given our basic setting with SUTVA, unconfoundedness and strong overlap, suppose that we construct  $\hat{\tau}_{AIPW}$  using cross-fitting with estimators satisfying, for  $w \in \{0, 1\}$  and also with the roles of  $\mathcal{I}_1$  and  $\mathcal{I}_2$  swapped,

$$\begin{aligned} o(n^{-\alpha_\mu}) \text{ RMSE/L}^2\text{-norm error} &\rightsquigarrow n^{-2\alpha_\mu} \frac{1}{|\mathcal{I}_1|} \sum_{i \in \mathcal{I}_1} \left( \hat{\mu}_{(w)}^{\mathcal{I}_2}(X_i) - \mu_{(w)}(X_i) \right)^2 \xrightarrow{p} 0, \\ o(n^{-\alpha_e}) \text{ RMSE/L}^2\text{-norm error} &\rightsquigarrow n^{-2\alpha_e} \frac{1}{|\mathcal{I}_1|} \sum_{i \in \mathcal{I}_1} \left( \frac{1}{\hat{e}^{\mathcal{I}_2}(X_i)} - \frac{1}{e(X_i)} \right)^2 \xrightarrow{p} 0, \end{aligned} \quad (3.11)$$

for some constants with  $\alpha_\mu, \alpha_e \geq 0$  and  $\alpha_\mu + \alpha_e \geq 1/2$ . Then (3.9) and thus also (3.5) hold.

$$\begin{aligned} \sqrt{n} (\hat{\tau}_{AIPW} - \tau) &\Rightarrow \mathcal{N}(0, V_{AIPW}), & \sqrt{n} (\hat{\tau}_{AIPW} - \hat{\tau}_{AIPW}^*) &\xrightarrow{p} 0 \\ V_{AIPW} &= \text{Var}[\tau(X_i)] + \mathbb{E} \left[ \frac{\sigma_0^2(X_i)}{1 - e(X_i)} \right] + \mathbb{E} \left[ \frac{\sigma_1^2(X_i)}{e(X_i)} \right] \end{aligned}$$

## Estimation and Inference with AIPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- Generalize into K-fold cross-fitting:

We define the data into  $K$  folds (above,  $K = 2$ ), and compute estimators  $\hat{\mu}_{(w)}^{(-k)}(x)$ , etc., excluding the  $k$ -th fold. Then, writing  $k(i)$  as the mapping that takes an observation and puts it into one of the  $k$  folds, we can write

Train	Train	Infer
Train	Infer	Train
Infer	Train	Train

K = 3

$$\begin{aligned} \hat{\tau}_{AIPW} &= \frac{1}{n} \sum_{i=1}^n \left( \hat{\mu}_{(1)}^{(-k(i))}(X_i) - \hat{\mu}_{(0)}^{(-k(i))}(X_i) \right. \\ &\quad \left. + W_i \frac{Y_i - \hat{\mu}_{(1)}^{(-k(i))}(X_i)}{\hat{e}^{(-k(i))}(X_i)} - (1 - W_i) \frac{Y_i - \hat{\mu}_{(0)}^{(-k(i))}(X_i)}{1 - \hat{e}^{(-k(i))}(X_i)} \right). \end{aligned} \quad (3.16)$$

(1 -  $\alpha$ )-Confidence Level:

$$\tau \in \left( \hat{\tau}_{AIPW} \pm \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \frac{1}{\sqrt{n}} \sqrt{\hat{V}_{AIPW}} \right)$$

Inverse CDF of standard normal.

$$\begin{aligned} \hat{\Gamma}_i &= \hat{\mu}_{(1)}^{(-k(i))}(X_i) - \hat{\mu}_{(0)}^{(-k(i))}(X_i) \\ &\quad + W_i \frac{Y_i - \hat{\mu}_{(1)}^{(-k(i))}(X_i)}{\hat{e}^{(-k(i))}(X_i)} - (1 - W_i) \frac{Y_i - \hat{\mu}_{(0)}^{(-k(i))}(X_i)}{1 - \hat{e}^{(-k(i))}(X_i)}. \end{aligned}$$

## (Optimal) Efficiency of AIPW

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)  
 Applied Causal Inference Powered by ML and AI: [https://chapters.causalmi-book.org/CausalML\\_book\\_2022.pdf](https://chapters.causalmi-book.org/CausalML_book_2022.pdf)  
 Duke STA640 Causal Inference: <https://www2.stat.duke.edu/~f135/CausalInferenceClass.html>

- AIPW achieves the same efficiency as the stratify-by-X method, which is actually optimal.

$$\hat{\tau}_{STRAT} = \sum_{x \in \mathcal{X}} \frac{n_x}{n} \hat{\tau}(x), \quad \hat{\tau}(x) = \frac{1}{n_{x0}} \sum_{\{X_i=x, W_i=1\}} Y_i - \frac{1}{n_{x0}} \sum_{\{X_i=x, W_i=0\}} Y_i \text{ where } n_x = |\{i : X_i = x\}| \text{ and } n_{xw} = |\{i : X_i = x, W_i = w\}|$$

**Theorem 3.4.** Under basic setting with SUTVA, unconfoundedness and strong overlap,  $V^*$  is the efficient variance for estimating the average treatment effect.

$$\sqrt{n}(\hat{\tau} - \tau^*) \Rightarrow \mathcal{N}(0, V^*)$$

$$V^* = \text{Var}[\tau(X_i)] + \mathbb{E}\left[\frac{\sigma_0^2(X_i)}{1 - e(X_i)}\right] + \mathbb{E}\left[\frac{\sigma_1^2(X_i)}{e(X_i)}\right]$$

- For a long time, (optimal) efficiency is not a good criterion for designing practical estimators for ATE.
  - Efficient estimators were considered fragile, complicated and/or impractical.
  - Econometric practice largely focused on methods under parametric assumptions (e.g., linear regression), or non-efficiently but conceptually simple (e.g., matching).
- The AIPW method (more generally, DML), however, makes efficient treatment effect estimators practical.

**Abstract.** We estimate the causal effects of different targeted email promotions on the opening and purchase decisions of the consumers who receive them. To do so, we synthesize and extend recent advances in causal machine learning techniques to capture heterogeneity in the content of the email subject line itself as well as heterogeneous consumer responses to the promotional offers and semantic choices contained therein. We find that content and framing are important for driving performance. We identify precise causal estimates of the effects of individual deal components, personalized content, and various semantic choices on consumer outcomes all the way down the conversion funnel. The decompositional nature of our methodology allows us to show how different combinations of key words and promotional inducements produce significantly different outcomes, both within a given stage and across all stages of the funnel. Notably, discounts framed as clearance events sharply outperform those tied to particular products. We also find components that drive engagement at the top of the funnel don't always lead to conversion at the bottom: their efficacy, across the funnel, is significantly moderated by the engagement levels of the consumers who receive them. Finally, leveraging both aspects of heterogeneity, we use off-policy evaluation to demonstrate the potential for significant gains from improved targeting.

## Doubly Robust Policy Evaluation

Causal Inference: A Statistical Learning Approach [https://web.stanford.edu/~swager/causal\\_inf\\_book.pdf](https://web.stanford.edu/~swager/causal_inf_book.pdf)

- AIPW-like DR methods have been widely adopted in the business literature for policy evaluation.

**Policy Evaluation (PE) Problem**

Distribution of feature  $x$       Randomized Policy  $v(\cdot|.)$

$$v(x, a, r) = D(x)v(a|x)D(r|a, x)$$

and hence  $V = \mathbb{E}_v[r]$ .

Expected Reward of Policy  $v(\cdot|.)$

Reward distribution given feature  $x$  and action  $a$

**1. Direct Method (DM)**

$$\hat{V}_{\text{DM}} = \frac{1}{n} \sum_{k=1}^n \sum_{a \in \mathcal{A}} v(a|x_k) \hat{r}(x_k, a)$$

Estimated Reward

**2. Inverse Propensity Score (IPS)**

$$\hat{V}_{\text{IPS}} = \frac{1}{n} \sum_{k=1}^n \frac{v(a_k|x_k)}{\hat{\mu}_k(a_k|x_k)} \cdot r_k$$

Estimated policy from which the data is sampled.

(3.1)  $\hat{V}_{\text{DR}} = \frac{1}{n} \sum_{k=1}^n \left[ \hat{r}(x_k, v) + \frac{v(a_k|x_k)}{\hat{\mu}_k(a_k|x_k)} \cdot (r_k - \hat{r}(x_k, a_k)) \right]$

where

$$\hat{r}(x, v) = \sum_{a \in \mathcal{A}} v(a|x) \hat{r}(x, a)$$

**Abstract.** We present an empirical framework for creating dynamic coupon targeting strategies for high-dimensional and high-frequency settings, and we test its performance using a large-scale field experiment. The framework captures consumers' intertemporal tradeoffs associated with dynamic pricing and does not rely on functional form assumptions about consumers' decision-making processes. The model is estimated using batch deep reinforcement learning (BDRL), which relies on Q-learning, a model-free solution that can mitigate model bias. It leverages deep neural networks to represent the high-dimensional state space and alleviate the curse of dimensionality. The empirical application is in a multibillion-dollar livestream shopping context. Our BDRL solution increases the platform's revenue by twice as much as static targeting policies and by 20% more than the model-based solution. The comparative advantage of BDRL comes from more effective and automatic targeting of consumers based on both heterogeneity and dynamics, using exceptionally rich, nuanced differences among consumers and across time. We find that price skimming, reducing discounts for attractive hosts, and increasing the coupon discount level at a faster rate for low spenders are effective strategies based on dynamics, consumer heterogeneity, and the two combined, respectively.

**Abstract.** Decision makers often want to target interventions so as to maximize an outcome that is observed only in the long term. This typically requires delaying decisions until the outcome is observed or relying on simple short-term proxies for the long-term outcome. Here, we build on the statistical surrogacy and policy learning literatures to impute the missing long-term outcomes and then approximate the optimal targeting policy on the imputed outcomes via a doubly robust approach. We first show that conditions for the validity of average treatment effect estimation with imputed outcomes are also sufficient for valid policy evaluation and optimization; furthermore, these conditions can be somewhat relaxed for policy optimization. We apply our approach in two large-scale proactive churn management experiments at *The Boston Globe* by targeting optimal discounts to its digital subscribers based on their observed covariates. Using the first field experiment, we evaluate this approach empirically by comparing the policy learned using imputed outcomes with a policy learned on the ground-truth, long-term outcomes. The performance of these two policies is statistically indistinguishable, and we rule out large losses from relying on surrogates. Our approach also outperforms a policy learned on short-term proxies for the long-term outcome. In a second field experiment, we implement the optimal targeting policy with additional randomized exploration, which allows us to update the optimal policy for future subscribers. Over three years, our approach had a net-positive revenue impact in the range of \$4–\$5 million compared with the status quo.
